# Cloud Platform Programming

## Lab Work

# Outline

- Practice Python
- Cloud Services

# Lab Work - Practice Python

- Problem 1: Develop an application that asks the user for her/his name, and then greets them with their name.

# Lab Work - Practice Python

- Problem 2: Write an application that displays the recommended weight given the user's age and height (in centimeters) using the following formula:

  RW = (height - 100 + age % 10) * 0.90

# Lab Work - Practice Python

- Problem 3: You have been asked to create an application for the Student Union shop which sells caps for 5, shirts for 10 and hoodies for 20. Your application should allow the user to input the quantity of each item a student wants to buy and then calculate and output the total cost. When you have finished the implementation, test your application to ensure that the calculations are correct.

# Lab Work - Practice Python

- Problem 4: Having just started college, Bob has been busy looking for a part-time job to fund his new college social life and after only two weeks of looking he has managed to get two job offers! Each job comes with different hours, basic rates of pay and over-time rates so he needs to work out which would get him the most money. Develop an application that would allow Bob to enter his basic pay rate, his number of regular hours work per week and his number of overtime hours per week. The application should then calculate and display Bob's total basic pay for the week, his overtime pay for the week and his total pay including overtime. Note: The overtime rate is 1.5 times the basic rate of pay.

# Lab Work – Introduction to Cloud Services

- We have discussed three as-a-Service cloud computing service models
  - Platform as a Service
  - Infrastructure as a Service
  - Software as a Service
- What are others X-as-a-Service that you can find? Each should research to find between 10-15 examples
- Identify three top provides in each X-as-a-Service model that you find
